

DID YOU KNOW...? SIGHT- THE UNSEEN SENSE

Most animals have difficulty seeing anything that doesn't move. For example, you're hiking in the mountains, and you come across a deer. What does it do? It freezes; it doesn't move. Why not? Because it believes you can't see it, because it can't see you, if you don't move. She believes her eyes and your eyes are the same. She knows the mountain lion's are, so how could yours be different?

But she's mistaken. We see stationary objects easily, so we still see her. However, all this time, haven't you thought that animals see just like you, or at least similar? Only primates and birds do.

Here's another example. You toss a biscuit to your dog, but he doesn't see where it went. How does he find it? With his nose. Why does he have to use his nose? Because his eyes don't see stationary objects well.

This vision impediment is now obvious to you. So how is it that you've never heard this topic discussed anywhere? Perhaps we don't see what's in front of us all of the time either. Ah. Something to think about—sight the seen and unseen.
